2015/2016 - 2019/2020

How long can a person spread the flu virus?

Most people may be able to spread the flu 1 day before showing symptoms up to 5 to 7 days after symptoms begin. Research suggests Tamiflu reduces the infectious period by 1 day.

Of those cases reported only 31% were noted to have received a flu shot for 2019-2020 season.

A Weekly Influenza Surveillance Report Prepared by the Influenza Division
Influenza-Like Illness (ILI) Activity Level Indicator Determined by Data Reported to ILINet
2019-20 Influenza Season Week 7 ending Feb 15, 2020

ILI Activity Level

- High
- Moderate
- Low
- Minimal
- Insufficient Data

*This map uses the proportion of outpatient visits to healthcare providers for influenza-like illness to measure the ILI activity level within a state. It does not, however, measure the extent of geographic spread of flu within a state. Therefore, outbreaks occurring in a single city could cause the state to display high activity levels.
*Data collected in ILINet may disproportionately represent certain populations within a state, and therefore may not accurately depict the full picture of influenza activity for the whole state.
*Data displayed in this map are based on data collected in ILINet, whereas the State and Territorial flu activity map are based on reports from state and territorial epidemiologists. The data presented in this map is preliminary and may change as more data is received.
*Differences in the data presented by CDC and state health departments likely represent differing levels of data completeness with data presented by the state likely being the more complete.
*For the data download you can use Activity Level for the number and Activity Level Label for the text description.
